

Xolisa

This GitHub Actions workflow automates a basic CI check that runs every time code is pushed to the `main` branch, or a pull request is opened. When triggered, GitHub spins up a fresh Ubuntu virtual machine, checks out the repository code and executes a shell command to confirm the pipeline is functioning.

The value of this automation is consistency and speed. Instead of relying on a developer to manually verify that nothing is broken, the CI workflow runs automatically and provides immediate feedback. In a team environment, this means every contribution is checked before it can be merged, reducing the risk of broken code reaching production.

This workflow purpose is to establish the foundation. In later projects, the same structure can be extended to run tests, lint code, build Docker images, or deploy applications. Understanding how triggers, jobs, and steps connect is what makes scaling up to more advanced pipelines straightforward
